Treatment Summary

Patient:	Christine Edwards
Treating provider:	Timothy York, DC
Diagnosis:	wrist fracture

The patient presented following a side-impact motor vehicle collision at an intersection with a right distal radius fracture confirmed on initail radiographs. Closed reduction was performed in the emergency setting, and the forearm was immobilized in a sugar-tong splint for the first two weeks of care. Subsequent imaging showed acceptable alignment, and the patient was transitioned to a short-arm cast with serial radiographs to monitor healing.

Over the course of treatment, the patient attended 27 outpatient visits. These included orthopedic follow-up, physical therapy sessions focused on range of motion, grip strength restoration, and progressive strengthening, and occupational therapy for activities of daily living. Pain was initially managed with scheduled analgesics, later reduced to as-needed use as symptoms improved.

At the most recent evaluation, the fracture showed radiographic evidence of union. The ptaient has regained approximately 80 percent of pre-injury wrist flexion and extension and reports improved grip function, though mild stiffness with repetitive gripping persists. Ongoing home exercise instructions were provided, with follow-up recommended as needed for residual symptoms.
