Treatment Summary

Patient:	David Krueger
Treating provider:	Clifford Reyes, DC
Diagnosis:	concussion

The patient presneted following a side-impact motor vehicle collision at an inetrsection and was evaluated for concussion with associated headache, dizziness, and intermittent neck pain. Initial assessment noted mild cognitive slowing and sensitivity to light and noise, with no loss of consciousness reported at the scene. Neurological examination was nonfocal, and cervical range of motion was reduced with paraspinal tenderness. Care over the course of 15 vistis included graded symptom management, vestibular and oculomotor exercises, cervical physical therapy, and gradual return to cognitive activities with periodic symptom monitoring. Symptoms improved steadily across the treatment period, with headaches decreasing in ferquency and intensity and dizziness resolving by the later visits. Residual neck stiffness persisted intermittently but improved with ongoing therapy. At the time of discharge from active care, the patient was tolerating daily activities and work duties with minimal restriction. Follow-up was recommended as needed for any recurrence of symptoms, and a home exercise program was provided to maintain progress.
