Treatment Summary

Patient:	Anne Bridges
Treating provider:	Michael Clark, DC
Diagnosis:	wrist fracture

Clinical Treatment Summary

Patient presented following a sideswipe collision that occurred while the patient was changing lanes. Initial evaluation revealed pain, swelling, and limited range of motion of the left wrist. Radiographs confirmed a distal radius fracture without significant displacement. The wrist was immobilized in a short arm cast, and the patient was advised on elevation, pain management, and activity restriction.

Over six visits, follow-up imaging demonstrated stable alignment and progressive callus formation. Cast immobilization was maintained for the expected healing period, after which the cast was removed and a removable wrist splint was issued for protected use. Range of motion exercises were introduced under supervision, and grip strength gradually improved. At the most recent visit, the patient reported decreased pain, improved function in daily activities, and was cleared for graduated return to work duties with lifting restrictions. Continued home exercise and periodic reassessment were recommended.
