Treatment Summary

Patient:	Amber Glass
Treating provider:	Jasmine Smith, DC
Diagnosis:	wrist fracture

The patient presented following a side-impact motor vehicle collision at an intersection, reporting pain and swelling of the left wrist. Initial radiographs confirmed a displaced distal radius fracture with no evidence of intra-articular extension. Closed reduction was performed under local anesthesia, followed by application of a short-arm cast with satisfactory alignment on post-reduction imaging.

Over the course of nine outpatient visits, the patient was monitored for swelling, neurovascular status, and pain control. Analgesia was managed with a combination of acetaminophen and a short course of a non-steroidal anti-inflammatory agent. Serial radiographs showed maintained alignment and early callus formation. The cast was removed at the appropriate interval, and a removalbe wrist splint was issued for protection during activity.

At the most recent visit, the patient dmeonstrated improving range of motion and grip strength, with residual stiffness in wrist extension. A structured physical therapy program was recommended. Prognosis for full functional recovery is good, with follow-up to be scheduled as needed.
