Treatment Summary

Patient:	William Young
Treating provider:	Rachel Bell, DC
Diagnosis:	shoulder injury

The patient presented following a motor vehicle collision involving a side impact at an intersection. Initial evaluation documented right shoulder pain, restricted range of motion with limietd abduction and external rotation, and tenderness over the anterior joint line. Imaging was reviewed and showed no fracture or dislocation; findings were consistent with a soft tissue injury, including a partial-thickness strain of the rotator cuff musculature.

Over the course of 15 supervised visits, the patient was treated with a combination of manual therapy, progresisve therapeutic exercise targeting scapular stabilization and rotator cuff strengthening, and modalities for pain control. Range of motion improved steadily, and pain decreased from moderate at intake to mild at discharge. Strength testing at the final visit showed near-symmetrical function compared with the uninjured side, with residual mild weakness on resisted overhead movement.

The patient was discharged to an independent home exercise program with instructions to continue activity modification and to reutrn if symptoms worsen. Prognosis for full functional recovery is good, with ongoing monitoring recommended if persistent discomfort develops.
