Treatment Summary

Patient:	Antonio Simmons
Treating provider:	Jasmine Smith, DC
Diagnosis:	knee injury

The patient presented following a rear-end motor vehicle collision with acute pain and swelling in the rihgt knee, limited weight-bearing, and tenderness along the medial joint line. Initial examination showed a moderate effusion and reduced range of motion, with no gross instability on stress testing. Imaging was reviewed and ruled out acute fracture, and the working diagnosis was a soft tisuse injury to the medial collateral ligament with associated meniscal irritation.

Over the course of 18 visits, treatmnet focused on pain and inflammation control, progressive range-of-motion exercises, quadriceps and hip strengthening, and gait retraining. The patient was also provided with a hinged knee brace for the early recovery phase. Symptoms improved steadily, with effusion resolving by the midpoint of care and range of motion approaching the contralateral side by discharge.

At the most recent evaluation, the patient reported residual stiffness after prolonged sititng and occasional discomfort on stairs, but was able to walk without an assistive device and resume most daily activities. Continued home exercise and activity modification were recommended, with follow-up as nedeed should symptoms recur or worsen.
