Treatment Summary

Patient:	Carl Bryant
Treating provider:	Clifford Reyes, DC
Diagnosis:	wrist fracture

Clinical Treatment Summary

Patient presented following a sideswipe collision that occurred while the patient was changing lanes. Initial evaluation revealed tenderness, swelling, and limtied range of motion of the affected wrist. Radiographs confirmed a distal radius fracture with mild dorsal displacement. Closed redutcion was performed in the emergency setting, and the wrist was immobilized in a short-arm cast.

Over the course of treatment, the patient attended 18 visits for orthopedic follow-up, serial radiographic monitoring, cast management, and progressive physical therapy. Alignment was maintained throughout healing. Cast was removed at the appropriate interval, and a structured rehabilitation program was initiated to restore grip strength, wrist flexion and extension, and forearm rotation.

At the most recent visit, the patient demonstrated near-full range of motion with mild residual stiffness and improving grip strength. Pain was reported as minimal with daily activities. Continued home exercise program and periodic reassessment are recommended. Work restrictions were lifted, with a caution against heavy lifting until full strength is regained.
