Treatment Summary

Patient:	Elizabeth White
Treating provider:	Clifford Reyes, DC
Diagnosis:	wrist fracture

Clinical Treatment Summary

Patient presented following a side-impact motor vehicle collision that occurred at an intersection. Examination at initial visit revealed pain, swelling, and limited range of motion of the affected wrist. Radiographic imaging confirmed a distal radius fracture without significant displacement. The wrist was immobilized in a splint and the patient was counseled on elevation, activity restriction, and pain management.

Over the course of ten outpatient visits, the patient was monitored for healing progress, neurovascular status, and functional recovery. Follow-up imaging demonstrated appropriate callus formation and maintained alignment. Immobilization was transitioned to a removable brace at the midpoint of care, and a structured home exercise program and supervsied range-of-motion tehrapy were initiated. Grip strength and wrist mobility improved steadily across visits.

At the most recent visit, the patient reported minimal pain, near-full range of motion, and return toward baseline grip strength. Discharge recommendations include continued home exercises, gradual return to work duties as tolerated, and follow-up as needed should symptoms recur.
