Treatment Summary

Patient:	Samantha Steele
Treating provider:	Austin Hill, DC
Diagnosis:	wrist fracture

Clinical Treatment Summary

Patient presented following a side-impact collision at an intersection with a complaint of right wrist pain and limited grip. Initial imaging demonstrated a distal radius fracture with mild dorsal angulation, without intra-articular extension. The wrist was immobilized in a voalr splint and the patient was counseled on elevation, icing, and analgesic use.

Over the course of twelve outpatient visits, the fracture was monitored radiographically at regular intervals and showed progressive healing with maintained alignment. Once early bony union was confirmed, the splint was discontinued and a structured rehabilitation program was initiated, focusing on range-of-motion exercises, grip strengthening, and graded return to daily activities. Pain decreased steadily and the patient's functional scores improved across the course of care.

At discharge from active treatment, the patient has near-full wrist range of motion with residual mild stiffness on extreme flexion. Grip strength is improving but not yet at baseline. Continued home exercise and periodic follow-up are recommended. Work restrictions were lifted at the final visit, with a plan to reassess if symptoms recur.
