Treatment Summary

Patient:	Brendan Smith
Treating provider:	Rodney Harrison, DC
Diagnosis:	neck strain

The patient presented following a side-impact motor vehicle collision at an intersection, reporting immediate onset of neck pain, stiffness, and intermittent headaches radiating to the right trapezius. Cervical range of motion was reduced by approximately 40 percent in rotation and lateral flexion, with paraspinal muscle tenderness and guarding noted on examination. Neurological screening was within normal limits, and no fracture was identified on initial cervical imaging. Diagnosis was cervical strain with associated myofascial pain.

Over the course of care, the patient completed 22 visits consisting of manual therapy, progressive therapeutic exercise, postural education, and transcutaneous electrical nerve stimulation as needed. Symptoms improved steadily, with pain scores decreasing and range of motion returning to near baseline by the final visits. Headache frequency decreased substantially. At discharge, the patient was ambulating without restriction, tolerating full work duties, and demonstarted independent home exercise competence. Residual mild stiffness with prolonged positioning was noted. Discharge to self-directed home program with follow-up as needed.
