Treatment Summary

Patient:	Jeffrey Andrews
Treating provider:	Rachel Bell, DC
Diagnosis:	wrist fracture

Clinical Treatment Summary

Patient presented following a rear-end motor vehicle collision with pain, swelling, and limited function of the left wrist. Imaging confirmed a distal radius fracture with mild displacement. Closed reduction was performed and the wrist was immobilized in a short arm cast for six weeks, with serial radiographs showing satisfactory alignment and early callus formation.

Over the course of treatment the patient attended 30 visits, including orthopedic follow-up, physical therapy sessions focused on range of motion and grip strength, and pain management reviews. Cast removal was followed by a structured rehabilitation program. At last evaluation, the patient had regained most wrist flexion and extension, grip strength was improved though still below the uninjured side, and residual stiffness and intermittent discomfort with heavy lifting were noted. Continued home exercises and activity modifications were recommended, with reassessment if symptoms worsen.
