## Treatment Summary

| | |
|---|---|
| **Patient:** | Sarah Wiggins |
| **Treating provider:** | Christopher Walton, DC |
| **Diagnosis:** | wrist fracture |

Treatment Summary

The patient presented following a low-speed head-on collision with pain, swelling, and limited range of motion in the right wrist. Radiographic evaluation confirmed a closed distal radius fracture with minimal displacement. Initial management consisted of immobilization in a volar splint, elevation, and anti-inflammatory medication. Closed reduction was not required given acceptable alignment.

Over the course of 26 visits, the patient was seen for serial radiographs to monitor fracture healing, followed by progressive physical therapy focused on restoring grip strength, wrist flexion and extension, and forearm rotation. Early visits addressed pain control and edema, while later visits emphasized strengthening, functional task training, and a gradual return to work duties.

At discharge, radiogarphs demonstrated satisfactory union. The patient reported marked improvement in pain and function, with residual mild stiffness and rdeuced grip strength compared to the uninjured side. Continued home exercise and periodic reassessment were recommended.
